

Practical Number : 8

1. Title: Perform frontend data validation and event intercept handling; develop a gym admission form with user profile registration and confirmation features.

2. Software/Tools Required: Visual Studio Code (VSCode), JavaScript, Web Browser (e.g., Google Chrome).

3. Theory:

Form validation and client-side data handling allow JavaScript to intercept, sanitize, and verify user credentials before saving data or updating a system layout.

- **Form Submission Interception:** Involves overriding the browser's default reload action when a user clicks submit. By targeting the element with `getElementById()` and invoking `event.preventDefault()`, JavaScript stops data from disappearing instantly.
- **Data Extraction & Regex Validation:** Enables capturing input field values on the fly (`document.getElementById('mobileNumber').value`). It relies on HTML attributes like `pattern` and structural logic to enforce email formats, character restrictions, and exactly 10-digit mobile limits.
- **Dynamic Content Injection:** Allows JavaScript to hide form components completely (`style.display = 'none'`) once validated, read the input fields, and dynamically write strings into specific confirmation text tags (`textContent = fullName`) to provide real-time visual receipts.

4. Output:

PRANATI'S FITNESS GYM

Start your fitness journey today

Full Name

Mobile Number

Email ID

Address

JOIN NOW

5. Result/Conclusion:

The Gym Admission Form application demonstrates how JavaScript interacts with form submission states to construct responsive web workflows. By combining event capturing listeners with targeted element value extractions, the application securely processes user string structures, enforces proper pattern formatting, and visually displays instant updates to confirm registration states.

Case Study : 8

1. Title: Online Job Application Form Using HTML, CSS, and JavaScript

2. Software/Tools Required: HTML, VS Code.

3. Theory: The Online Job Application Form is developed using HTML, CSS, and JavaScript. HTML is used to create the form structure and input fields such as name, email, phone number, qualification, and job role. CSS is used to style the form and improve its appearance. JavaScript is used to validate user inputs, check empty fields, validate email and phone numbers, and handle the form submission event. DOM manipulation is used to display success and error messages dynamically.

4. Output:

The screenshot shows a web browser window with multiple tabs. The active tab is titled 'Online Job Application'. The address bar shows the URL '127.0.0.1:5500/index.html'. The main content area displays a form titled 'Online Job Application Form'. The form contains the following fields:

- Full Name:** A text input field.
- Email:** A text input field.
- Phone Number:** A text input field.
- Qualification:** A dropdown menu with 'B.Tech' selected.
- Job Role:** A dropdown menu with 'Software Developer' selected.

Below the form fields is a green button labeled 'Apply Now'. Below the button, a green message states 'Application submitted successfully!'.

Conclusion : In this case study, we successfully created an Online Job Application Form using HTML, CSS, and JavaScript. We implemented form validation, event handling, and dynamic message display. This activity helped us understand how JavaScript can be used to access form elements, validate user input, and improve the functionality of web forms.
